

TMDL Nutrient Targets for Nearshore Waters of Lake Pend Oreille, ID – An Evaluation Using Long-Term Trophic and Periphyton Productivity Monitoring Data

Kristin Larson and Robert Steed
Idaho Department of Environmental Quality
National Water Quality Monitoring Conference
May 2-4, 2016

Lake Pend Oreille

- 329 km² (91,297 acres)
- mean depth = 164 m
- maximum depth = 357 m
- 111 miles of shoreline

5th deepest and
8th largest
natural lake in
the US

Lake Pend Oreille

- Largely surrounded by undeveloped forest - Much of it is managed by the US Forest Service
- Much of the terrain around the lake is very steep, which also precludes development.

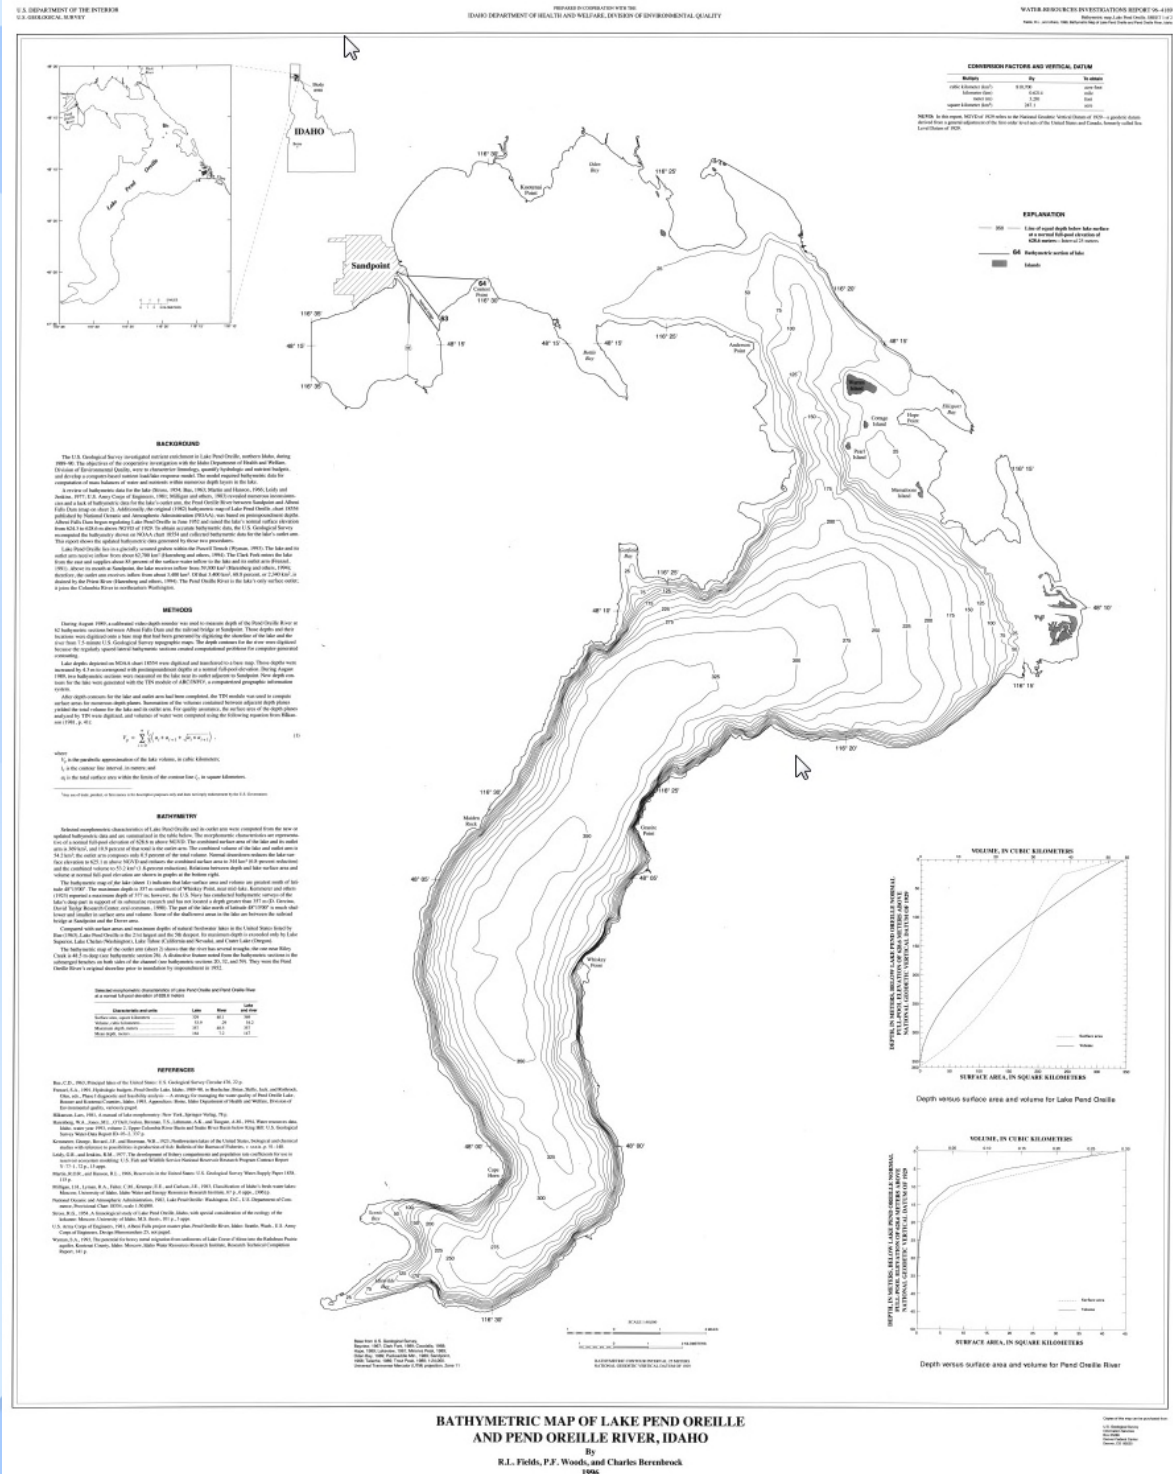

Lake Pend Oreille

Development is in isolated locations around the lake
The biggest area being Sandpoint, ID on the northern shoreline of the lake.

Sandpoint and its surrounding area population is about 10,000 people (2010 Census)

- Lake Pend Oreille is divided it into two basins:
 - the deep southern end that contains approximately 95% of the lake's volume with HRT > 10 years .
 - the relatively well-flushed, shallow northern basin with HRT <1 year.

Lake Pend Oreille

- In 1987, Congress mandated a comprehensive water quality study in the Clark Fork-Pend Oreille Basin. Results (Frenzel 1991):
- Approximately 90% of the nitrogen and phosphorus load to Lake Pend Oreille comes from the Clark Fork River.
- The trophic status of the nearshore areas of Lake Pend Oreille was changing much more rapidly than the open waters.
- Development may be impacting water quality and productivity in the nearshore waters of the lake

**Total Maximum Daily Load (TMDL) for Nutrients for
the Nearshore Waters of Pend Oreille Lake, Idaho**

January, 2001

Are practices that have been implemented helping to reduce pollutants from entering the lake?

- Education
- Citizen Monitoring
- Development/Shoreline Ordinances
- Invasive Species Control
- Pump-out Facilities
- Wastewater Treatment Upgrades
- Clark Fork Delta Habitat Restoration
- Pack River Habitat Restoration

TMDL Targets

- 9 $\mu\text{g}/\text{L}$ target to represent an average total phosphorus concentration throughout the nearshore waters of the lake.
- Targets are based on the assumption that the impairment to the nearshore waters is from periphyton (attached bottom algae) in the littoral zone of the lake.

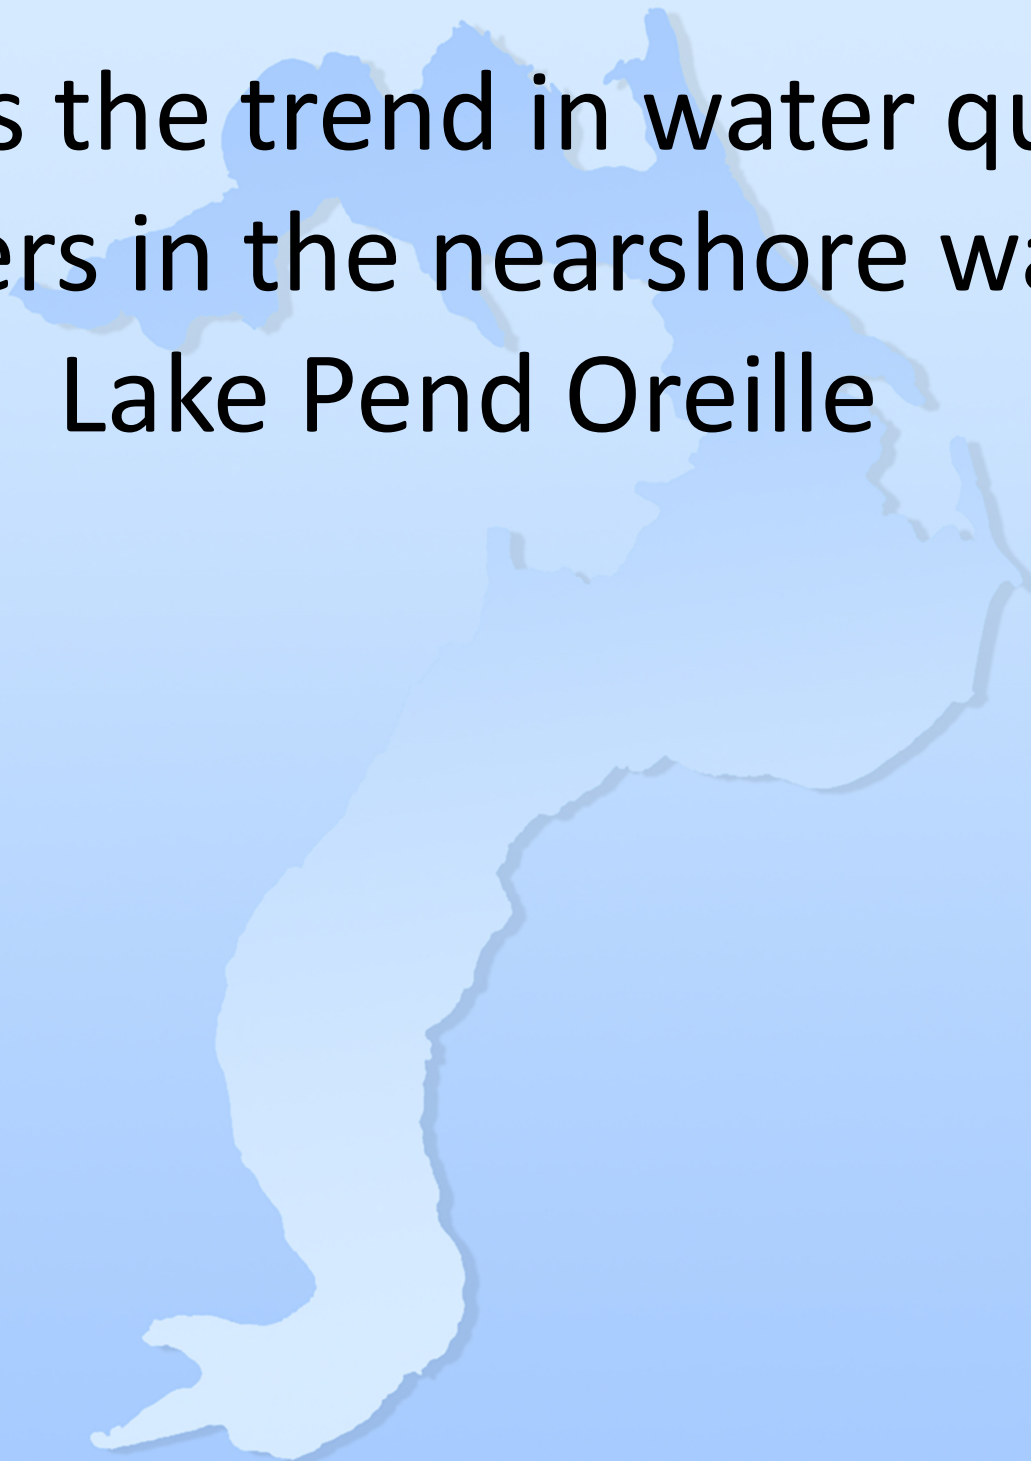

TMDL 5-Year Review Approach

The goals of the five-year review of the *TMDL for Nutrients for the Nearshore Waters of Pend Oreille Lake, Idaho* are to answer the following questions:

- What is the trend in water quality parameters in the nearshore waters of Lake Pend Oreille
- Are water quality targets in the TMDL being met?
- How does the water quality and targets in the TMDL relate to productivity in the nearshore waters of Lake Pend Oreille?
- The TMDL assumes that the dominant factor affecting nearshore water quality is loading from the immediate nearshore drainage area, not from tributaries. Is this assumption valid?
- What practices have been implemented to reduce pollutants from entering the lake?

What is the trend in water quality parameters in the nearshore waters of Lake Pend Oreille

Water Quality Monitoring

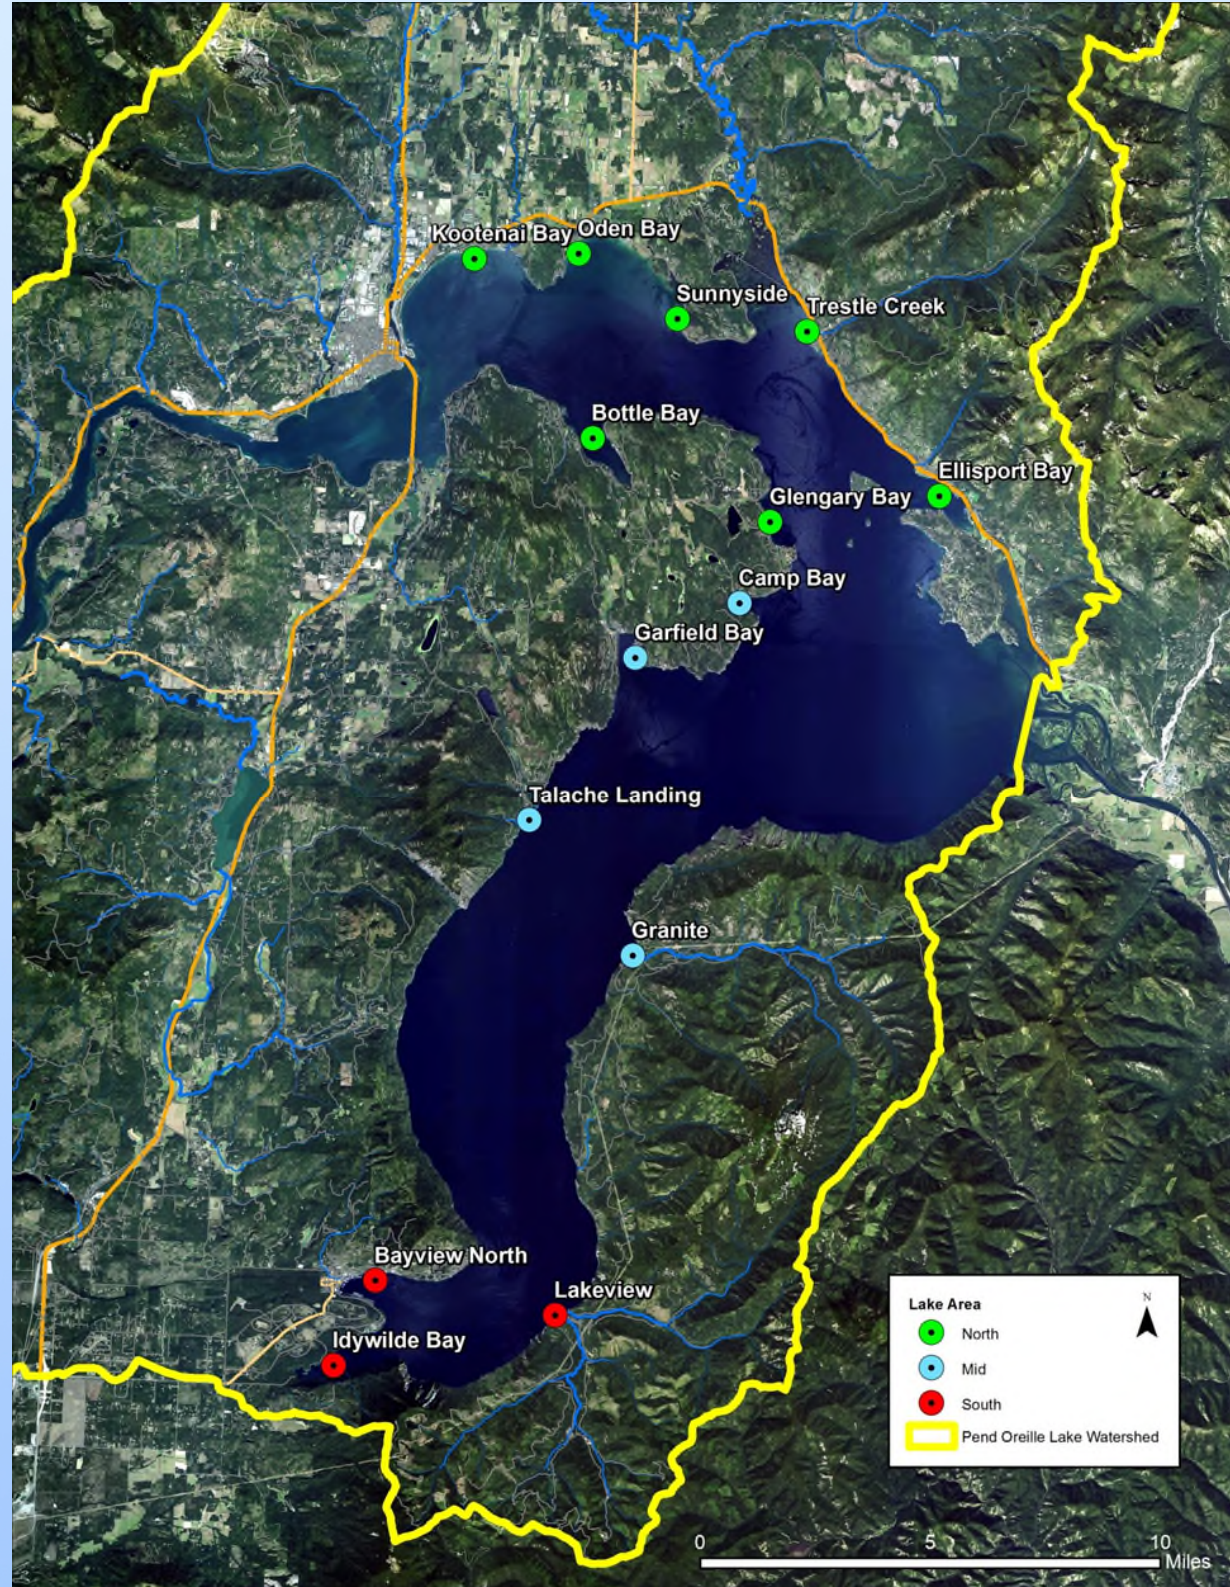

- C. M. Falter (U of I)
Studies: 1989, 1990,
2003
- Tri-State Water Quality
Council: 2006-2008
- IDEQ: 2009, 2012,
2013, 2014

Trophic Monitoring

- monthly from June through September
- Profiles through the water column: temperature, pH, dissolved oxygen, electrical conductivity, and secchi depth
- Photic zone aquatic chemistry composite for analysis of total nitrogen, total phosphorus, and chlorophyll a.
- If the site is stratified, a grab sample is taken from the hypolimnion for analysis of total nitrogen, and total phosphorus.

Median Total Phosphorus by location

Median Total Phosphorus by Month

Median Total Phosphorus by Month

Chlorophyll-a

Are water quality targets in the TMDL
being met?

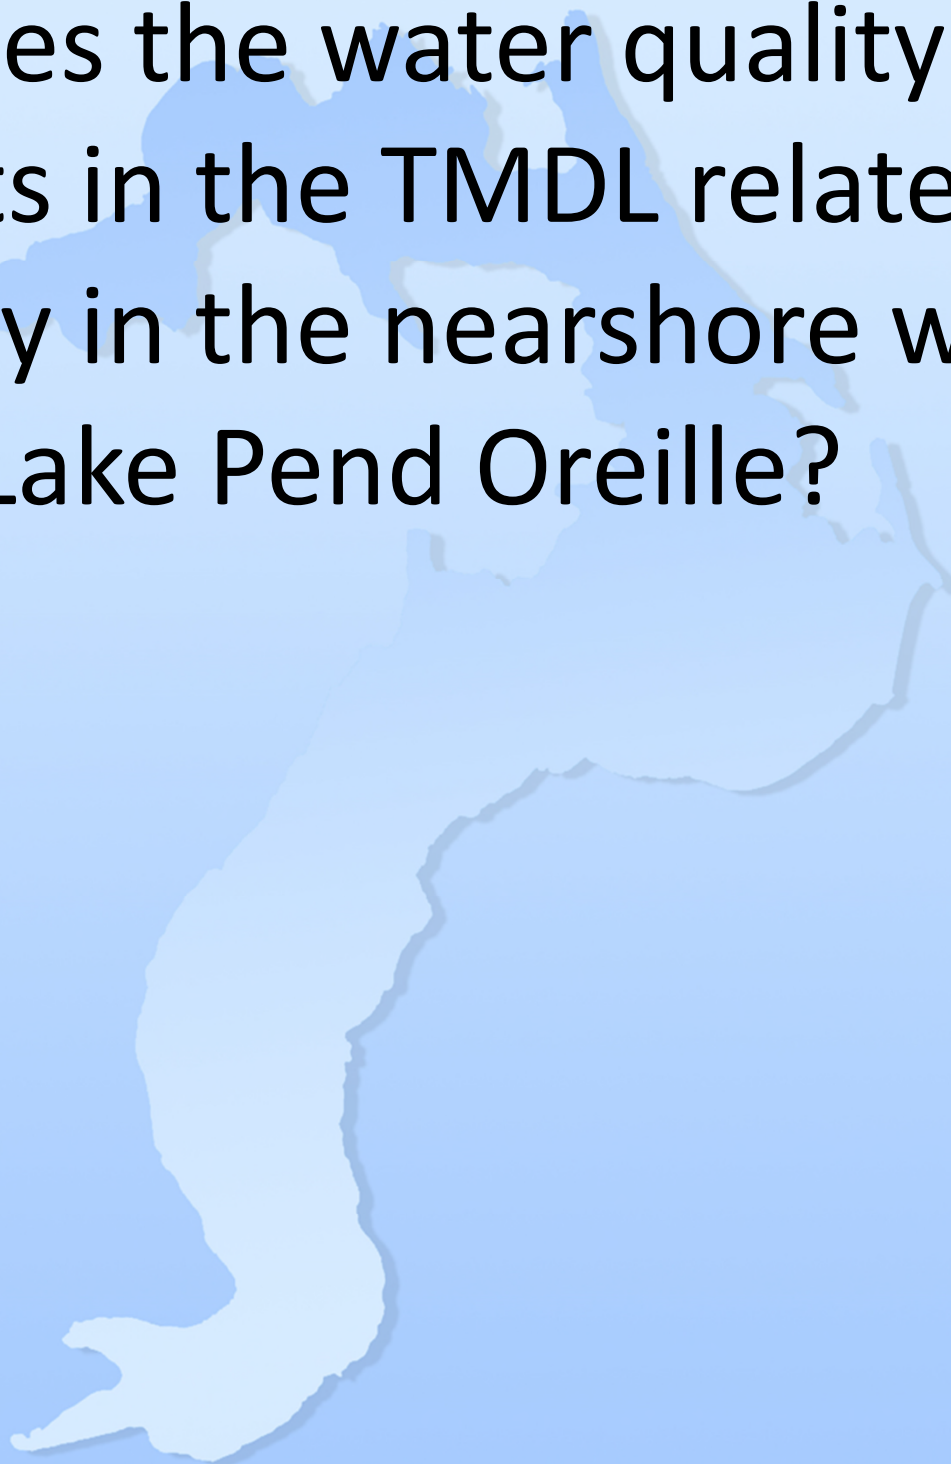

Binomial Distribution Analysis

$$P(x \text{ "successes"}) = \frac{n!}{x! (n-x)!} p^x (1-p)^{(n-x)}$$

- Non-parametric analysis with a statistical approach to evaluate the *probability* of the TMDL target being exceeded based on the number of samples taken.
- Reduces the number of false positive and false negative errors
- Results determined the targets are not being met in the northern nearshore region of the lake, but they are being met in the mid and southern regions

How does the water quality and targets in the TMDL relate to productivity in the nearshore waters of Lake Pend Oreille?

Productivity Monitoring

- Another aspect of limnological investigations is the evaluation of benthic algae or periphyton,
- In addition to being the primary food source for aquatic insects, periphyton are considered early indicators for change in chemical and physical environmental factors within a lake.

Productivity Monitoring

- Artificial substrates were deployed at all nearshore stations, and they were visited weekly for the following 6 weeks.
- Periphyton samples were collected and analyzed for chlorophyll *a* concentrations each week to determine a rate of growth and a relative measure of productivity.
- During the retrieval, an additional periphyton sample was taken for periphyton taxa identification and enumeration.

Artificial Substrates

- Consists of an expanded polystyrene block mounted to plywood .
- The plywood is bolted to a piece of concrete flagstone to provide added support and ballast.

Figure 5. Illustration of artificial substrate.

Garfield	<u>South</u>	340,000	31,000	240,000	8,800	62,000	

Summary

- The northern stations have the highest human influence and also the highest productivity.
- Chlorophyll *a* data suggest that water column nutrients in the northern portion of the lake support higher periphyton productivity than do the nutrients in the southern portion.
- If nutrients increase in the nearshore areas, it is likely that nuisance aquatic growths will further impair beneficial uses.
- The targets are appropriate for the nearshore areas of the lake

The TMDL assumes that the dominant factor affecting nearshore water quality is loading from the immediate nearshore drainage area, not from tributaries.

Is this assumption valid?

- The loading calculations did not take into account other loading sources to the lake. The following sources were not considered in the TMDL:
 - The Clark Fork River
 - The Pack River
 - Other tributaries to the lake
 - Specific stormwater from greater Sandpoint area, Hope, and Bayview

Summary of TMDL 5-Year Review

- **The TMDL targets of 9 $\mu\text{g}/\text{L}$ and 12 $\mu\text{g}/\text{L}$ are reasonable targets and should remain in place.**
- TMDL targets are not being met in northern region of the lake, and are being met in the mid and southern region of the lake.
- TP concentrations were significantly higher in north than in the mid and southern lake regions.
- TP concentration in the mid and southern have not changed significantly over time.
- Productivity in the northern lake is higher than the mid and southern regions of the lake.
